## Parameterized Complexity Assignment 4.

1. Given  $\rightarrow$  A graph  $G(V, E)$  & an integer  $k$ .

Parameter  $\rightarrow k$ .

Goal  $\rightarrow$  Find  $S \subseteq V(G)$  of size at most  $k$  ( $|S| \leq k$ )  
S.T.  $G - S$  does not contain a cycle of length  $\geq 7$ .

### Reduction Rules.

Rule 1. Degree 0 & 1 vertices.

Forward

We can safely remove the vertices with degree 0 & 1 as they do not contribute in making of a cycle.

Backward.

Adding vertices of degree 0 & 1 in the reduced graph does not change the cyclic nature of graph as they don't contribute in cycle formation.

Rule 2. Degree 2 vertices.

If a vertex  $v$  has a degree 2 & is adjacent to vertices  $u$  &  $w$  then remove  $v$  & add an edge between  $u$  &  $w$ . It does not create a new cycle.

②

Rule 3 Vertices with degree  $\geq 2$ .

For vertices with  $d \geq 2$ , we can remove all but two of its incident edges. This is because vertices with  $d \geq 2$  can't be part of a cycle of length 7.

Assume a vertex  $v$  with degree  $\geq 2$ . As  $v$  can't be the part of cycle of length 7 it means that  $v$  must have at least  $d-1$  leaf neighbours. This is because in each cycle each vertex has exactly 2 neighbours.

If we have  $d \geq 2$  edges incident on  $v$ , we can keep only two of them & remove the rest. This ensures that  $v$  still has at least  $d-1$  leaf neighbours. The removed edges do not contribute to any cycle. So we can discard/Remove them.

Observation

Forward:

Applying the reduction rules decrease the size of graph. Rule 1, 2, 3 will reduce the vertices of graph & Rule 4 reduces the #edges.

Backward:

For any set  $S \subseteq V(G)$  after applying the reduction rules adding back the vertices removed in Rule 1, 2, 3

$\&$  restoring by rule 4 produces a graph that is valid / same as of given graph.

### Kernel Size

1. Removing all the vertices with degree 0 does not change the value of  $k$ . So no effect on kernel size.
2. Removing all the vertices with degree 1 we decrease the value of  $k$  by 1 for each vertex. This can remove atmost  $k$  vertices.
3. Removing a vertex of degree 2 & connecting its neighbours does not change value of  $k$ . So no effect on kernel size.
4. For each vertex removed by rule 4, we remove atmost 2 edges. Therefore this rule can remove atmost  $2k$  edges.

$$\begin{aligned}\text{Thus the kernel size} &\Rightarrow 2k + 12 + k + 4 \\ &\Rightarrow \underline{4k + 16 \text{ atmost}}\end{aligned}$$

### Runtime Analysis.

1. Scanning all vertices to identify isolated vertices takes  $O(V(G))$  time.
2. Removing vertices of degree 1. This is also be done

(4)

Date:

Page:

in  $O(V(G))$  time.

3. Handle vertices of degree 2. We iterate through the vertices of  $G$  once & apply this rule. & can be done in  $O(V(G) + E(G))$  time.
4. Handle vertices of degree  $\geq 3$ . This can be done in  $O(V(G) + E(G))$  time.

Thus total time is  $O(V(G) + E(G))$  & it runs in polynomial time.

(b) We have a kernel size of  $4k+4$ .

The algorithm runs in  $O(V(G) + E(G))$

→ In the worst case we have to do  $2^k$  recursive calls.

→ For each time it is taking  $O(n^2)$  time.

Thus total time is  $O(V(G) + E(G) + \underbrace{n^2 2^k}_{\downarrow})$

branching

As our kernel size is of  $4k+4$  so enumerating each set will take  $2^{4k+4}$  iteration which is bounded by  $6 \cdot 27^k$  for  $k \geq 6$

For each time deleting the cycle time taken is  $O(n^2)$  via DFS to detect cycles.

Overall Runtime is  $O(6.27^k \cdot n^2)$  or

$$\Rightarrow O(6.27^k \cdot n^{O(1)})$$
